

## I - INTRODUCTION

The purpose of this project was three-fold: to understand in detail the complete neglect of differential overlap (CNDO) approximate molecular orbital theory of Pople, Santry, and Segal<sup>1</sup> as well as the intermediate neglect of differential overlap (INDO) theory of Pople, Beveridge, and Dobosh;<sup>2</sup> to adapt a computer program of these theories to the computer facilities available to Sweet Briar and in so doing to gain an insight into algorithmic solutions to quantum chemical problems; and to apply the modified program to a simple problem, a comparison of the effects of chlorine and fluorine on the  $\sigma$  and  $\pi$  electron densities in a series of substituted acetylenes and ethylenes.

## II - THEORETICAL

Quantum mechanical theory has been developed to the extent that the Schrodinger equation for any hypothetical or real two-body system can be solved exactly. (An example of a two-body system would be a system with one electron and one nucleus.) A problem with more than one electron around one nucleus, and, in the more complicated cases, more than one nucleus, presents insurmountable difficulties in the exact solution of the Schrodinger equation due to the increased complexity of the Hamiltonian and concurrently of the partial differential equation which must be solved. The time-independent Schrodinger equation for the hydrogen atom, for example, is

$$(1) \quad \left\{ -\frac{\hbar^2}{2m} \nabla^2 - \frac{Ze^2}{r} \right\} \Psi(r) = E \Psi(r)$$

where  $\hbar$  is Planck's constant/ $2\pi$ ,  $m$  is the mass of the electron,  $\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$ ,  $Ze$  is the charge of the nucleus ( $Z=1$  for hydrogen),  $e$  is the unit of electronic charge and  $r$  the distance between the electron and the nucleus. In this expression the first term represents the quantum mechanical operator for the kinetic energy of the system while the second is the potential energy of the electron in the field of the nucleus. Though this equation is a partial differential equation of the second degree with three variables it can be solved by separation of variables as discussed in most quantum mechanics textbooks.<sup>3</sup>

In contrast to the above soluble differential equation is the Schrodinger equation for the many-electron, many center problem which must include the interactions between all the electrons and between the electrons and nuclei. The Hamiltonian for

DR.RUPNATHJI( DR.RUPAK NATH )

such a system is given by

$$(2) H^{\text{total}}(1, 2, \dots, N; 1, 2, \dots, n) = -\frac{\hbar^2}{2} \sum_A \nabla_A^2 M_A^{-1} V_A^{-2} + \sum_{A=e} Z_A^2 e^2 \sum_e \gamma_{Ae}^{-1} - \frac{\hbar^2}{2m} \sum_P \nabla_P^2 - \sum_A \sum_P e^2 \frac{Z_A}{R_{AP}} + \sum_{i,j} e^2 \gamma_{ij}^{-1}$$

In the above expression  $M_A$  = the mass of nucleus A, m and e are electronic mass and charge,  $Z_A e$  is the charge of nucleus A, and  $r_{ij}$  is the distance between electron i and electron j. (Note that capital subscripts refer to nuclei and subscripts in the lower case to electrons.) Inspection of the Hamiltonian reveals that kinetic energy terms for all the nuclei and electrons are included as well as the potential energy due to the interaction of each particle with all other particles of the system.

The Schroedinger equation for a system with n particles and N nuclei thus becomes a partial differential equation of  $3N + 3n$  variables, each variable being described by three cartesian coordinates.

$$(3) H^{\text{total}}(1, 2, \dots, N; 1, 2, \dots, n) \Psi(1, 2, \dots, N; 1, 2, \dots, n) = E \Psi(1, 2, \dots, N; 1, 2, \dots, n)$$

This equation cannot be solved exactly.

Though solutions to the Schroedinger equation for the H atom are of great theoretical interest, there has been a continuous effort among chemists to extend the practical application of the equation to more complicated systems through scientifically sound and meaningful approximations. A recent approximation developed by Pople, Santry and Segal is the complete neglect of differential overlap (CNDO) theory;<sup>1</sup> the intermediate neglect of differential overlap (INDO) theory of Pople, Beveridge, and Dobosh<sup>2</sup> is derived from the CNDO framework.

DR.RUPNATHJI( DR.RUPAK NATH )

The CNDO method indirectly utilizes several general approximations which are common to many approximate molecular orbital theories as well as specific approximations which make it unique. One such general approximation is the Born-Oppenheimer approximation which states that the nuclei of a system can be considered stationary relative to the motion of the electrons in their fields. In reality the nuclei of a system are in motion as are the electrons. The mass of any nucleus is so much greater than the mass of an electron that its velocity can be neglected when compared with the much greater velocity of an electron. In the case of the hydrogen nucleus, for example, where this approximation introduces the greatest amount of error, the mass of the nucleus is over 1800 times that of the electron; thus even here the error is small. This assumption reduces the complexity of the problem considerably; one must calculate only  $n$  wavefunctions and energies corresponding to the  $n$  electrons in motion around  $N$  stationary nuclei. The Hamiltonian of equation (3) becomes

$$(4) \quad H^{elec} = -\frac{\hbar^2}{2m} \sum_P \nabla_P^2 - \sum_A \sum_P e^2 z_A r_{AP}^{-1} + \sum_{p < q} e^2 r_{pq}^{-1}$$

and the Schroedinger equation

$$(5) \quad H^{elec}(\psi_{1,2,\dots,n}) \psi^{elec}(1,2,\dots,n) = \epsilon \psi(1,2,\dots,n)$$

It is important to note here that due to the Born-Oppenheimer approximation only the electronic energy eigenvalues are calculated. In order to include the internuclear repulsion one must add

$$(6) \quad \sum_{A < B} e^2 z_A z_B r_{AB}^{-1}$$

DR.RUPNATHJI( DR.RUPAK NATH )

with  $Z_A e$  the charge on nucleus A,  $Z_B e$  the charge on nucleus B and  $r_{AB}$  the internuclear distance. The expression for the total energy of a system using the Born-Oppenheimer approximation is therefore

$$(7) \quad E^{\text{total}} = E^{\text{elec}} + \sum_{A < B} e^2 Z_A Z_B r_{AB}^{-1}$$

Molecular orbital theory is chiefly concerned with the wavefunctions which describe the motion of electrons with respect to the nuclei, as this motion results in the phenomenon of a covalent chemical bond between two or more nuclei. The Born-Oppenheimer approximation's focus on electronic wavefunctions is viable if this is kept in mind, and this approximation thus can be considered "scientifically sound."

A second fundamental approximation utilized in approximate molecular orbital theories is the orbital approximation. The underlying assumption of this approximation is that a satisfactory many-electron molecular orbital wavefunction  $\Psi$  can be constructed from a product of functions  $\phi_i$ , each of which depends on the coordinates of one electron only.

$$(8) \quad \Psi(\phi_1, \phi_2, \dots, \phi_n) = \phi_1(1) \phi_2(2) \phi_3(3) \dots \phi_n(n)$$

(The parenthetical numbers in equation 8 refer to electronic coordinates.) By definition each function  $\phi_i$  is known as an orbital, in the case of an atom, an atomic orbital and in the case of a molecule, a molecular orbital. As Pople and Beveridge point out,<sup>4</sup> if the true Hamiltonian could be constructed as a sum of operators depending only on the coordinates of one electron, then a separation of variables approach could yield exact solutions to the

DR.RUPNATHJI( DR.RUPAK NATH )

Schroedinger equation for the system. This, as has been shown, however, is not the case (see equation (3)), and the assumption that the molecular wavefunction is of the above form introduces an approximation and some degree of error.

As well as these general approximations, a specific theoretical framework - the variational method - is used in the CNDO and other approximate molecular orbital methods as a general approach to the solution of the complex problem. This method is based on the variational theorem which, according to Dewar,<sup>5</sup> states that "the expectation value of H for an arbitrary well-behaved function  $\Psi$  is not less than the lowest eigenvalue  $E_0$  of H" where the expectation value E is given by

$$(9) \quad E = \frac{\int \Psi^* H \Psi \, d\tau}{\int \Psi^* \Psi \, d\tau}$$

For proof of this theorem the reader may refer to Molecular Quantum Mechanics by P. W. Atkins<sup>6</sup> as well as other quantum chemistry texts. If one applied the variational method to a completely flexible wavefunction with an infinite number of variable parameters one could obtain all the correct wavefunctions and eigenvalues for the Hamiltonian. Such an application is not feasible for mathematical as well as practical reasons, however, but the approach can be applied to incompletely flexible functions which can be varied and minimized with respect to only a given few parameters. The set of functions thus obtained are approximations to the true wavefunctions, and the energies corresponding to the  $\Psi_i$  are functions of the variable parameters. The variation theorem, then, provides a method for adjusting the variable parameters of some arbitrary trial wavefunction to opti-

DR.RUPNATHJI( DR.RUPAK NATH )

mize the correspondence of that wavefunction to the true wavefunction. (For example, if  $E(k)$  is found to be an eigenvalue of some arbitrary wavefunction  $\Psi(k)$ , the variation method calls for minimization of  $E(k)$  with respect to  $k$  ( $\partial/\partial k E(k)=0$ ) and a solution for the minimum value of  $k$ . Substitution of the minimum value of  $k$  into  $E(k)$  will yield  $E_{\min}$ , and substitution of the minimum value of  $k$  into  $\Psi(k)$  will, according to the variational theorem, give the best approximate wavefunction using the given parameter.) A convenient choice of eigenfunctions in the variational method is often a set of functions which are linear combinations of atomic orbitals. (LCAO).

$$(10) \quad \Psi_i = \sum_{\mu} c_{\mu i} \phi_{\mu}$$

where  $\phi_{\mu}$  are atomic orbitals and  $c_{\mu i}$  are weighting coefficients. A further requirement imposed by the LCAO approximation is that the molecular orbitals be orthonormal. That is,

$$(11) \quad \sum_{\mu\nu} c_{\mu i}^* c_{\nu j} S_{\mu\nu} = \delta_{ij}$$

where  $\delta_{ij}$  is the Kronecker delta and  $S_{\mu\nu}$  is the overlap integral

$$(12) \quad S_{\mu\nu} = \int \phi_{\mu}(i) \phi_{\nu}(i) d\tau.$$

The above brief discussion of some of the important general approximations and the methods used in approximate molecular orbital theories leads to a more rigorous analysis of the CNDO and INDO methods. The following formulations of these theories will deal with closed-shell systems only.

As well as being based on the above general approximations, the CNDO method is a simplification of the LCAO approach to the

DR.RUPNATHJI( DR.RUPAK NATH )

Hartree-Fock, self-consistent field (SCF) method. The LCAO/SCF approach leads to Roothaans algebraic equations.

The Hartree-Fock equations are

$$(13) \quad F \Psi_i = \varepsilon_i \Psi_i \quad i = 1, n$$

where

$$(14) \quad F = [H^{core} + \sum_j (2 J_{ij} - K_{ij})]$$

$$(15) \quad J_{ij}(1) = \int \Psi_i^*(2) \frac{1}{r_{12}} \Psi_i(2) d\tau_2$$

and

$$(16) \quad K_{ij}(1) \Psi_i(1) = \left[ \int \Psi_j^*(2) \frac{1}{r_{12}} \Psi_i(2) d\tau_2 \right] \Psi_j(1)$$

In the above equations  $H^{core}$  refers to the Hamiltonian of an electron in the field of a bare nucleus and  $r_{12}$  to the interelectronic distance. The eigenvalues of the above Hamiltonian  $F$  are

$$(17) \quad \varepsilon_i = H_{ii}^{core} + \sum_j (2 J_{ij} - K_{ij})$$

where

$$(18) \quad J_{ij} = \iint \Psi_i^*(1) \Psi_j^*(2) \frac{1}{r_{12}} \Psi_i(1) \Psi_j(2) d\tau_1 d\tau_2$$

and

$$(19) \quad K_{ij} = \iint \Psi_i^*(1) \Psi_j^*(2) \frac{1}{r_{12}} \Psi_j(1) \Psi_i(2) d\tau_1 d\tau_2$$

$J_{ij}$  and  $K_{ij}$  are known as "Coulomb" and "exchange" integrals respectively.  $J_{ij}$  represents the repulsion between electron 1 in orbital  $\Psi_i$  and electron 2 in orbital  $\Psi_j$  when the electrons are moving independently of each other. (Note that  $\Psi_i^* \Psi_i$  and  $\Psi_j^* \Psi_j$  by definition each represent a charge distribution, the probability of finding an electron in a given position.) Similarly the exchange integral  $K_{ij}$  has the physical interpretation that it represents the reduction in electron repulsion between two electrons in different

DR.RUPNATHJI( DR.RUPAK NATH )

orbitals with parallel spins.?

If the molecular orbitals  $\Psi_i$  are approximated as linear combinations of atomic orbitals, Roothaans equations are obtained. Substitution of the LCAO expansion of equation (10) into the Hartree-Fock equations yields

$$(20) \sum_{\nu} (F_{\mu\nu} - \epsilon_i S_{\mu\nu}) c_{\nu i} = 0$$

where

$$(21) F_{\mu\nu} = H_{\mu\nu} + \sum_{\lambda\sigma} P_{\lambda\sigma} [(\mu\nu|\lambda\sigma) - 1/2(\mu\lambda|\nu\sigma)]$$

$$(22) H_{\mu\nu} = \int \phi_{\mu}(1) H^{core} \phi_{\nu}(1) d\tau_1$$

$$(23) P_{\lambda\sigma} = 2 \sum_i^{occ} c_{\lambda i}^* c_{\sigma i}$$

and

$$(24) (\mu\nu|\lambda\sigma) = \int \phi_{\mu}(1) \phi_{\nu}(1) \frac{1}{r_{12}} \phi_{\lambda}(2) \phi_{\sigma}(2) d\tau_1 d\tau_2$$

The quantity  $(\mu\nu|\lambda\sigma)$  is known as an electron interaction integral; electron (1) is assumed to be on the left-hand side of the operator and electron (2) on the right-hand side.

The equations (20) may be written in matrix form and transformed to the form of a standard eigenvalue problem. If this is done the elements  $\epsilon_i$  will be roots of the secular determinant

$$(25) |F_{\mu\nu} - \epsilon S_{\mu\nu}| = 0$$

and each element  $\epsilon_i$  will be an energy eigenvalue of the molecular orbital  $\Psi_i$ . In equation (21)  $H_{\mu\nu}$  is the expectation value for the core Hamiltonian interacting with electron (1) in atomic orbital  $\phi_{\mu}$  and electron (1) in atomic orbital  $\phi_{\nu}$ . (Note that suffixes  $\mu$  and  $\nu$  refer to molecular orbital  $\Psi_i$ , and  $\lambda$  and  $\sigma$  to molecular orbi-

DR.RUPNATHJI( DR.RUPAK NATH )

tal  $\Psi_j$ .) In equation (23)  $P_{\lambda\sigma}$  is summed over the occupied molecular orbitals only, and the matrix composed of the elements  $P_{\lambda\sigma}$  is referred to as the density matrix.

The series of steps used in solving the secular determinant in equation (25) is equivalent to that used in the more approximate CNDO approach. An initial set of linear expansion coefficients is assumed from which is determined an initial density matrix (see equation (23)). A first guess at the matrix elements  $F_{\mu\nu}$  can then be made. After diagonalization a new set of coefficients is computed, and the process is repeated until a comparison of old and new values of the coefficients or some other chosen parameter is within a specified tolerance limit.

The LCAO/SCF method can be applied without modification to simple systems, but computational limitations have resulted in the growth of more approximate self-consistent field methods which seek to avoid the evaluation of many of the electron repulsion integrals, most of which actually have values near zero when calculated. Pople proposed the combinations of the zero differential overlap (ZDO) approximation<sup>8</sup> with a semiempirical determination of other parameters for the  $\pi$  electrons of aromatic systems.<sup>9</sup> The ZDO approach is based on systematic neglect of the overlap of certain pairs of electrons in different orbitals. According to this approximation:

$$(26) \quad (\mu\nu | \lambda\sigma) = (\mu\mu | \lambda\lambda) \delta_{\mu\nu} \delta_{\lambda\sigma}$$

where  $\delta_{ij}$  is the Kronecker delta. Further, the corresponding overlap integrals

$$(27) \quad S_{\mu\nu} = \int \phi_{\mu}(i) \phi_{\nu}(i) d\tau,$$

are neglected in the normalization of the molecular orbitals.

DR.RUPNATHJI( DR.RUPAK NATH )

It is important to note, however, that the core integrals

$$(28) \quad H_{\mu\nu} = \int \phi_{\mu}(i) H^{\text{core}} \phi_{\nu}(i) d\tau_i$$

involving an overlap distribution are not neglected by this method; the terms have a possible effect on bonding.

Thus while not ignoring all such interactions as does the Huckel method, the ZDO treatment is not as rigorous as the above complete LCAO/SCF approach. Pople, Santry, and Segal's formulation of CNDO theory<sup>1</sup> signifies a significant advance in approximate molecular orbital theory in that the ZDO approximation is extended to a system involving all valence electrons rather than just the  $\pi$  electrons of the molecule, the inner electrons being treated as part of a rigid, non-polarizable core.

Pople, Santry, and Segal<sup>1</sup> as well as Pople and Beveridge<sup>10</sup> discuss the importance of maintaining invariance with respect to certain transformations of the set of basis functions  $\phi_{\mu}$  at all levels of application of the ZDO approximation. These transformations are (1) transformations mixing orbitals of the same principle and azimuthal quantum numbers  $n$  and  $l$  (a mixing of  $2p_x$  and  $2p_y$  orbitals, for example) and (2) transformations mixing any atomic orbitals on the same atom (hybridization of orbitals, for example.) The LCAO/SCF method will lead to the same wavefunctions and properties regardless of these transformations; any approximation to the method, however, might remove this invariance.

Because the ZDO approximation is applied to atomic orbitals only, the differential overlap  $\phi_{\mu}\phi_{\nu}$  may be monotomic (atomic orbitals centered on the same atom) or diatomic (atomic orbitals centered on different atoms.) In the case of a monotomic overlap

DR.RUPNATHJI( DR.RUPAK NATH )

$\phi_\mu \phi_\nu$  on the same atom, the simple rotation of axis transformation such as transformation (1) may lead to variant results unless this possibility is considered in the development of the theory.

In the CNDO method in particular the ZDO approximation is used for all products of different atomic orbitals  $\phi_\mu \phi_\nu$ . To restore invariance under all transformations a further approximation is added to those of the ZDO approximation - that the electron interaction integrals which remain depend only on the atoms A and B to which the orbitals  $\phi_\mu$  and  $\phi_\nu$  belong and not on the type of orbital.

$$(29) \quad (\mu\mu | \nu\nu) = \gamma_{AB} \left\{ \begin{array}{l} \text{all } \mu \text{ on atom A} \\ \text{all } \nu \text{ on atom B} \end{array} \right\}$$

$\gamma_{AB}$  physically measures an average repulsion between an electron in one of the valence orbitals of atom A and an electron in one of the valence orbitals of atom B.

If the atomic orbitals of the basis set are transformed into orbitals which themselves are linear combinations of the original atomic orbitals,

$$(30) \quad \phi'_a = \sum_{\mu}^A t_{\mu a} \phi_\mu$$

$$(31) \quad \phi'_\beta = \sum_{\nu}^A t_{\nu\beta} \phi_\nu$$

$$(32) \quad \phi'_\gamma = \sum_{\lambda}^B t_{\lambda\gamma} \phi_\lambda$$

$$(33) \quad \phi'_\delta = \sum_{\sigma}^B t_{\sigma\delta} \phi_\sigma$$

then it can be shown that equation (29) restores invariance.

The electron interaction  $(\mu\nu | \lambda\sigma)$  becomes

$$(34) \quad (\alpha\beta | \gamma\delta) = \gamma_{AB} \int_{\gamma\delta} \mathcal{E}_{\alpha\beta}$$

DR.RUPNATHJI( DR.RUPAK NATH )

based on the orthonormality of the transformation matrices  $t$ . (In equation (34)  $\delta_{ij}$  is the Kronecker delta.) These transformations thus do not cause equation (29) to vary.

Application of the ZDO approximation to the elements of the Fock Hamiltonian matrix of equation (21) gives

$$(35) F_{\mu\mu} = H_{\mu\mu} + \sum_{\lambda} P_{\lambda\lambda} [(\mu\mu|\lambda\lambda) - 1/2 (\mu\lambda|\mu\lambda)] \\ = H_{\mu\mu} - 1/2 P_{\mu\mu} (\mu\mu|\mu\mu) + \sum_{\lambda} P_{\lambda\lambda} (\mu\mu|\lambda\lambda)$$

For the case in which  $\mu \neq \nu$

$$(36) F_{\mu\nu} = H_{\mu\nu} - 1/2 P_{\mu\nu} (\mu\mu|\nu\nu)$$

Adding the further approximations of equation (29), the diagonal Fock matrix elements become

$$(37) F_{\mu\mu} = H_{\mu\mu} - 1/2 P_{\mu\mu} \gamma_{AA} + \sum_B P_{\mu B} \gamma_{AB} \quad (\phi_{\mu} \text{ on } A)$$

and the elements for which  $\mu \neq \nu$  become

$$(38) F_{\mu\nu} = H_{\mu\nu} - 1/2 P_{\mu\nu} \gamma_{AB}$$

In equation (37) the population matrix  $P_{\mu B}$  is the total electron density on atom B.

$$(39) P_{\mu B} = \sum_{\lambda}^B P_{\lambda\lambda}$$

The core Hamiltonian operator, which consists of the potential due to the nucleus and the inner non-valence shells, is also modified according to the approximations proposed. **If**

$$(40) H = -1/2 \nabla^2 - \sum_B V_B$$

where  $-V_B$  is the core potential of atom B, the diagonal elements

DR.RUPNATHJI( DR.RUPAK NATH )

elements  $H_{\mu\mu}$  of the Hamiltonian may be thought of as a sum of one-center and two-center terms. (A one-center term is a term involving only one atom, while a two-center term involves interatomic interaction between two atoms.) These diagonal elements represent the interaction of an electron in  $\phi_\mu$  centered on atom A with the core of A as well as with the cores of other atoms. Separating into one and two-center contributions

$$(41) H_{\mu\mu} = U_{\mu\mu} - \sum_{B \neq A} \langle \mu | V_B | \mu \rangle \quad (\phi_\mu \text{ on } A)$$

where

$$(42) U_{\mu\mu} = \langle \mu | -\frac{1}{2} \nabla^2 - V_A | \mu \rangle$$

$$(43) \langle \mu | V_B | \mu \rangle = \int \phi_\mu V_B \phi_\mu \, d\tau$$

and

$$(44) \langle \mu | -\frac{1}{2} \nabla^2 - V_A | \mu \rangle = \int \phi_\mu (-\frac{1}{2} \nabla^2 - V_A) \phi_\mu \, d\tau$$

According to equation (44)  $U_{\mu\mu}$  is a one-center term, and since  $\phi_\mu$  is on atom A, the integral represents the interaction of an electron in orbital  $\phi_\mu$  with its own core potential. The second term of equation (41) relates the potentials of all other atoms B to the electron in orbital  $\phi_\mu$  on atom A; it is the two-center contribution to the core Hamiltonian element  $H_{\mu\mu}$ .

The off-diagonal terms deal with two different atomic orbitals  $\phi_\mu$  or  $\phi_\nu$  which may both be on atom A or which may be on different atoms. When  $\phi_\mu$  and  $\phi_\nu$  are both on atom A

$$(45) H_{\mu\nu} = U_{\mu\nu} - \sum_{S(\neq A)} \langle \mu | V_S | \nu \rangle \quad (\phi_\mu, \phi_\nu \text{ on atom } A)$$

Because the choice of a hybrid basis set (not s, p, d functions) leads to non-zero  $U_{\mu\nu}$  elements in equation (45), the CNDO method is restricted to the use of s, p, d functions. This choice for a

DR.RUPNATHJI( DR.RUPAK NATH )

basis set causes  $U_{\mu\nu}$  to be zero by symmetry. The second term in equation (45) represents the interactions of the charge distribution  $\phi_{\mu}\phi_{\nu}$  with the cores of other atoms B. These terms lead to a further approximation which is consistent with the ZDO approximation, that these interactions are set equal to zero unless  $\phi_{\mu}=\phi_{\nu}$ , in which case they are considered equal for all valence orbitals on A. No differentiation is made between types of orbitals based on quantum numbers. This approximation allows invariance to be maintained. According to these added approximations

$$(46) \quad \langle \mu | V_B | \nu \rangle = 0$$

$$(47) \quad \langle \mu | V_B | \mu \rangle = V_{AB}$$

$$(48) \quad H_{\mu\mu} = U_{\mu\mu} - \sum_{B(A)} \sum_{\nu(B)} \frac{V_{\mu\nu}}{r_{\mu\nu}} \quad (\mu \text{ on atom A})$$

and

$$(49) \quad H_{\mu\nu} = 0 \quad (\mu \neq \nu, \phi_{\mu}, \phi_{\nu} \text{ on atom A})$$

The remaining matrix elements  $H_{\mu\nu}$  to be considered are the elements dealing with atomic orbitals  $\phi_{\mu}$  and  $\phi_{\nu}$  on different atoms A and B. Neglecting three-center terms, the CNDO method assumes that  $H_{\mu\nu}$  is dependent only on the potential of the two atoms in question and not on the potentials of any other atoms. The term  $H_{\mu\nu}$  thus deals with the effect of two electrostatic fields on the energy levels of an electron and is referred to as the "resonance integral"  $\beta_{\mu\nu}$ . In this case

$$(50) \quad H_{\mu\nu} = \langle \mu | -\frac{1}{2} \nabla^2 - V_A - V_B | \nu \rangle = \beta_{\mu\nu}$$

The final approximation of the CNDO method deals with the

DR.RUPNATHJI( DR.RUPAK NATH )

estimation of a value for the resonance integral,

$$(51) H_{\mu\nu} = \beta_{\mu\nu} = \beta_{AB}^{\circ} S_{\mu\nu}$$

where  $S_{\mu\nu}$  is the overlap integral. This approximation formulates  $\beta_{\mu\nu}$  in terms of a known integral  $S_{\mu\nu}$  (one which has already been calculated) and an empirical parameter  $\beta_{AB}^{\circ}$  which is adjusted to achieve the best energy values for a given system. In order to maintain invariance, however, the parameter  $\beta_{AB}^{\circ}$  must be the same for all orbitals on the two atoms in question. It can be dependent on interatomic distance, however.

The approximations thus employed by the CNDO method are

(a) the zero differential overlap approximation

$$(52) (\mu\nu | \lambda\sigma) = (\mu\mu | \nu\nu) S_{\mu\nu} S_{\lambda\sigma}$$

which also calls for the neglect of the overlap integral  $S_{\mu\nu}$  in the normalization of the molecular orbitals and sets  $S_{\mu\nu} = 0$  unless  $\mu = \nu$

(b) the averaging of the electron interaction integral between  $\phi_{\mu}$  on A and  $\phi_{\lambda}$  on B

$$(53) (\mu\mu | \lambda\lambda) = V_{AB} \left\{ \begin{array}{l} \phi_{\mu} \text{ on A} \\ \phi_{\lambda} \text{ on B} \end{array} \right\}$$

(c) the approximation of the interaction of  $\phi_{\mu}\phi_{\nu}$  with other cores as zero if  $\phi_{\mu} \neq \phi_{\nu}$  and  $V_{AB}$  if  $\phi_{\mu} = \phi_{\nu}$

$$(54) \langle \mu | V_B | \nu \rangle = 0$$

$$(55) \langle \mu | V_B | \mu \rangle = V_{AB}$$

and lastly

(d) the approximation of resonance integrals through use of a proportionality factor

$$(56) H_{\mu\nu} = \beta_{AB}^{\circ} S_{\mu\nu} \quad (\phi_{\mu} \text{ on A, } \phi_{\nu} \text{ on B})$$

The final Fock matrix elements reduce to

DR.RUPNATHJI( DR.RUPAK NATH )

$$(57) F_{\mu\mu} = U_{\mu\mu} + (P_{AA} - 1/2 P_{\mu\mu}) \gamma_{AA} + \sum_{B \neq A} (P_{B\mu} \gamma_{AB} - V_{AB})$$

$$(58) F_{\mu\nu} = \beta_{AB}^0 S_{\mu\nu} - 1/2 P_{\mu\nu} \gamma_{AB} \quad (\mu \neq \nu)$$

where  $\phi_{\mu}$  is on A and  $\phi_{\nu}$  on B. If  $\phi_{\mu}$  and  $\phi_{\nu}$  are both on the same atom A

$$(59) F_{\mu\nu} = -1/2 P_{\mu\nu} \gamma_{AA}$$

The diagonal elements  $F_{\mu\mu}$  may be written

$$(60) F_{\mu\mu} = U_{\mu\mu} + (P_{AA} - 1/2 P_{\mu\mu}) \gamma_{AA} + \sum_{B \neq A} [-Q_B \gamma_{AB} + (Z_B \gamma_{AB} - V_{AB})]$$

where  $Q_B$  is the net charge on atom B.

$$(61) Q_B = Z_B - P_{BB}$$

The quantity  $Z_B \gamma_{AB} - V_{AB}$  is known as a penetration integral and is the difference between the potentials due to the valence electrons and the core of atom B.

After developing the CNDO theory, Pople and Segal follow with a discussion of possible methods for calculation and choice of parameters.<sup>11</sup> The original formulation is known as the CNDO/1 parameterization. They since have proposed a second and more successful method, the CNDO/2 parameterization.<sup>12</sup> As well as choosing a basis set, in the CNDO method one must empirically determine or otherwise specify values for the overlap integral  $S_{\mu\nu}$ , the core Hamiltonian elements  $U_{\mu\mu}$ ,  $V_{AB}$ , the electron-repulsion integrals  $\gamma_{AB}$  and the bonding parameters  $\beta_{AB}^0$ .

A logical choice of basis functions would seem to be the hydrogenic wavefunctions. These wavefunctions, however, are expressed as products of an angular and a radial part, the latter

DR.RUPNATHJI( DR.RUPAK NATH )

of which is mathematically complex and necessitates the evaluation of difficult integrals. For this reason the atomic orbitals in the CNDO method are chosen to be combinations of the spherical harmonics  $Y_{lm}(\theta, \phi)$  (the angular hydrogenic solution) and Slater functions<sup>13</sup> radial-like functions which are less complex than the true radial hydrogenic solutions. Slater functions are nodeless with an orbital exponent  $J$  which is determined by application of an empirical set of rules, Slater's rules. (In the CNDO approximation the exponent for hydrogen, however, is given a value of 1.2 instead of 2.6, the value determined by Slater's rules; 1.2 is more in accord with the best value for the constant <sup>according to</sup> the LCAO calculation for the hydrogen molecule.) The CNDO/1 parameterization was originally formulated only for molecules composed of atoms H through F.

The overlap integral  $S_{\mu\nu}$  is generally calculated in the following way: the overlap integral may be written

$$(62) S_{ab} = \int \Omega_{ab}(i) dt$$

where  $\Omega_{ab}$  is a charge distribution function and is a product of any two Slater-type-orbitals (STO)  $\chi_a$  and  $\chi_b$  which are themselves specified by principle, azimuthal and magnetic quantum numbers  $(n, l, m)$ .

$$(63) \Omega_{ab}(i) = \chi_a(i) \chi_b(i) \quad \left\{ \begin{array}{l} \chi_a \text{ on atom A} \\ \chi_b \text{ on atom B} \end{array} \right\}$$

If  $\chi_a$  and  $\chi_b$  are on the same atom,

$$(64) \begin{array}{ll} S_{ab} = 0 & \chi_a \neq \chi_b \\ S_{ab} = 1 & \chi_a = \chi_b \end{array}$$

DR.RUPNATHJI( DR.RUPAK NATH )

The charge distribution  $\Omega_{ab}(i)$  is written as a product of the analytical form of the STO's in spherical coordinates. If

$$(65) \chi_a(r, \theta, \phi) = N_a r^{n_a-1} \exp(-\int_a r) Y_{l_a m}(\theta, \phi)$$

$\Omega_{ab}(i)$  becomes

$$(66) \Omega_{ab}(i) = N_a N_b r_A^{n_a-1} r_B^{n_b-1} \exp(-\int_a r_A - \int_b r_B) \times \Theta_{l_a m}(\cos \theta_a) \Theta_{l_b m}(\cos \theta_b) \Phi_{m}^2(\phi)$$

(The functions  $\Theta_{l_a m}(\cos \theta_a)$ ,  $\Phi_m(\phi)$  are the real normalized spherical harmonics  $Y_l^m(\theta, \phi)$ .)  $\Omega_{ab}(i)$  is transformed to elliptical coordinates and the integration is carried out over  $\phi$ . The result of this integration is the reduced overlap integral, an expression involving one or more basic two-center integrals which is subsequently integrated over the  $\mu$  and  $\nu$  coordinates to yield the value for the overlap integral.

The electron repulsion integral  $\gamma_{AB}$  is calculated as a two-center integral involving valence s functions.

$$(67) \gamma_{AB} = \iint S_A^2(1) \frac{1}{r_{12}} S_B^2(2) d\tau_1 d\tau_2$$

Using Slater s functions

$$(68) \gamma(n_a, n_b, \int_a, \int_b, R) = \iint \Omega_{aa}(1) \frac{1}{r_{12}} \Omega_{bb}(2) d\tau_1 d\tau_2$$

where R is the distance between atom A and atom B, and  $\Omega_{aa}(1)$  and  $\Omega_{bb}(2)$  are the products of Slater s functions and represent charge distributions. The operator  $\frac{1}{r_{12}}$  is developed according to a given expansion, and the coulomb integral rearranged accordingly,

$$(69) \gamma(n_a, n_b, \int_a, \int_b, R) = \int \Omega_{aa}(1) I(n_b, \int_b, 1) d\tau_1$$

DR.RUPNATHJI( DR.RUPAK NATH )

where I is the potential of electron 2 at the position of electron 1.

$$(70) I(n_b, J_b, 1) = \int \frac{1}{r_2} \Omega_{bL}(2) d\tau_2$$

In equation (70)  $\frac{1}{r_2}$  is the final form of the operator  $\frac{1}{r_2}$  based on the development according to the expansion.  $r_2$  represents the greater value between  $r_1$  and  $r_2$  where  $r_1$  and  $r_2$  are the radii arrived at in the expansion and transformation to spherical polar coordinates.

The two-center coulomb integral is then solved in two steps, the first being an evaluation of the potential  $I(n_b, J_b, 1)$  by integration of equation (70) over spherical polar coordinates centered on b and the second a multiplication of the results of the first step by  $\Omega_{aL}(1)$  and integration over the coordinates of electron 2 in elliptical coordinates. The second integration is done through use of the reduced overlap integral.

The third empirically determined value,  $V_{AB}$ , representing the interaction of a valence electron of atom A with the core charge of atom B, is calculated through use of a valence s orbital on A and through the assumption that the core charge of atom B is centered at a point in the nucleus rather than dispersed throughout the nucleus and inner shells (as likely is the case).

$$(71) V_{AB} = Z_B \int S_A^2(1) \left( \frac{1}{r_{1B}} \right) d\tau_1$$

$Z_B$  is the core charge of atom B, and  $r_{1B}$  is the distance between electron 1 and nucleus B. This integral is handled in the same general way as the overlap integral with s being a Slater s type orbital.

Calculation of the atomic matrix elements of the one-electron core Hamiltonian  $U_{\mu\mu}$  is based on observed atomic energy

DR.RUPNATHJI( DR.RUPAK NATH )

levels. Applying the CNDO approximations, atoms from Li through F have energies

$$(72) E(X, 2s^m 2p^n) = m U_{2s, 2s} + n U_{2p, 2p} + \frac{1}{2} (m+n)(m+n-1) \gamma_{AA}$$

where X is the atom in question and  $\gamma_{AA}$  is the CNDO approximation of the electron repulsion integrals. Equation (72) refers to an electronic state, and since degeneracy occurs due to the neglect of exchange integrals in the CNDO method, an average of the energies of all the states having the given configuration is used in calculating the  $U_{\mu\mu}$  elements. Further, the  $U_{\mu\mu}$  integrals are related to ionization potentials or electron affinities of given states, experimental values of either of the two being used in the determination of  $U_{\mu\mu}$ . The  $\gamma$  parameters previously determined are also used in this calculation.

Having empirically calculated  $U_{\mu\mu}$ , the only remaining parameter to be specified is  $\beta_{AB}^{\circ}$ .  $\beta_{AB}^{\circ}$  is assumed to be a sum of contributions from atom A and atom B.

$$(73) \beta_{AB}^{\circ} = \frac{1}{2} (\beta_A^{\circ} + \beta_B^{\circ})$$

The values of  $\beta_A^{\circ}$  and  $\beta_B^{\circ}$  are chosen to give the best fit with accurate LCAO/SCF calculations using the valence shell basis set. These values, then, are based on the assumption that the LCAO/SCF calculations are the best calculations obtainable.

With the determination of the parameters  $S_{\mu\nu}$ ,  $U_{\mu\mu}$ ,  $V_{AB}$ ,  $\gamma_{AB}$  and  $\beta_{AB}^{\circ}$ , the solution of the problem calls for a cycle of steps similar to that discussed for the LCAO/SCF method. The initial guess of the molecular orbital coefficients is made by setting  $F_{\mu\mu}$  equal to the appropriate ionization potentials for the state

DR.RUPNATHJI( DR.RUPAK NATH )

being considered and by setting  $F_{\mu\nu} = S_{\mu\nu} \beta_{AB}^{\circ}$ . The latter is similar to the familiar Hückel approximation in that all off-diagonal elements are set equal to constants,  $S_{\mu\nu} \beta_{AB}^{\circ}$ . Diagonalization of this extended-Hückel approximation to the Fock matrix yields a set of eigenvectors (the coefficients) and eigenvalues (orbital energies). Electrons are then paired, and the pairs assigned to the molecular orbitals with lowest energies. Using the values of the coefficients, the density matrix is computed, which subsequently is used in the determination of new coefficients. The cycle is thus

- (a) an initial guess at the Fock matrix by a Huckel-like approximation
- (b) diagonalization of the matrix to yield a set of energies and molecular orbital coefficients
- (c) determination of the density matrix  $P_{\mu\nu}$  from the coefficients computed in (b)
- (d) formation of a new Fock matrix using the density matrix of (c) (see equations (57), (58), and (59))

Steps (b), (c), and (d) are repeated until a given parameter remains within a specified limit, at which time the molecular orbitals determined are declared "self-consistent."

The CNDO/2 parameterization<sup>12</sup> attempts to rectify some of the discrepancies between calculated CNDO/1 molecular properties and corresponding experimentally determined values. When testing the CNDO/1 parameterization Pople and Segal found that it was unsatisfactory if used to estimate equilibrium internuclear bondlengths.<sup>10</sup> For example, the bond length computed for HF was 0.581 Å, well below that experimentally determined, 0.92 Å. As a result, the dissociation energies calculated were also well

DR.RUPNATHJI( DR.RUPAK NATH )

off from the experimental data. It was found that the penetration integrals ( $\sum_B \gamma_{AB} - V_{AB}$ ) were the source of the problem since they gave rise to bonding energies when there should have been none. The CNDO/2 method accordingly neglects altogether this term by

$$(74) V_{AB} = \sum_B \gamma_{AB}$$

Due to equation (74) the penetration integral obviously becomes zero.

The second difference between the CNDO/1 and CNDO/2 theories deals with the computation of  $U_{\mu\mu}$ . In the CNDO/1 theory ionization potentials were used or, alternatively, electron affinities. The CNDO/2 procedure is to use an average of both ionization potentials and electron affinities to account for the tendency of the atomic orbital to lose and gain electrons. The CNDO/2 alterations of CNDO/1 parameterizations cause equation (57) to become

$$(75) F_{\mu\mu} = -1/2 (I_{\mu} + A_{\mu}) + [(P_{AA} - Z_A) - 1/2 (P_{\mu\mu} - 1)] \gamma_{AA} + \sum_{B(+A)} (P_{BB} - Z_B) \gamma_{AB}$$

where  $I_{\mu}$  is the ionization potential of atomic orbital  $\phi_{\mu}$  and  $A_{\mu}$  is the electron affinity of the orbital.

Aside from modifications in the method for determination of  $U_{\mu\mu}$  and the neglect of the penetration integral, the features of the CNDO/2 theory are the same as those of the CNDO/1 theory. In the CNDO/2 method other parameters are calculated as in the CNDO/1 method, and the same self-consistent-type cycle is used to obtain a solution. These two changes, however, improve the success of the calculations with respect to bond lengths and dissociation energies.

DR.RUPNATHJI( DR.RUPAK NATH )

The CNDO/1 and CNDO/2 parameterizations were originally proposed for molecules composed of atoms through atomic number 9 (fluorine) with a maximum of 4 basis functions per atom ( $2s$ ,  $2p_x$ ,  $2p_y$ , and  $2p_z$ ). The difficulties of extending the theory through the second row of elements (through chlorine) are practical ones. Few accurate LCAO/SCF calculations for heavier atoms are available for comparison of results, and atomic energy levels of the 3d atomic orbitals are also difficult to obtain. Santry and Segal attempt to extend the theory,<sup>14</sup> however, considering first a basis set of five 3d atomic orbitals with the same radial part as the 3s and 3p functions (the spd set) and second, a basis set with more accurate d functions (the spd' set). The latter involves modifications in the CNDO/2 theory but will not be discussed because the former is the basis set for the heavier atoms sodium to chlorine in the computer program to be discussed in the next section.

Calculations using an spd basis set rely on the CNDO/2 parameterization as discussed above with a difference in the method of estimating bonding parameters  $\beta_{AB}^{\circ}$ .

$$(76) \quad \beta_{AB}^{\circ} = \frac{1}{2} K (\beta_A^{\circ} + \beta_B^{\circ})$$

If A is a second-row element and C a first-row element,  $\beta_A^{\circ}$  is approximated by the proportionality relation

$$(77) \quad \beta_A^{\circ} = \beta_C^{\circ} \frac{U_{3s,3s}(A) + U_{sp,sp}(A)}{U_{2s,2s}(C) + U_{2p,2p}(C)}$$

where U refers to the core Hamiltonian elements. The proportionality constant K is set equal to unity if only first row atoms are involved but is given a value of 0.75 if either A or B is a second-

DR.RUPNATHJI( DR.RUPAK NATH )

row element. Such a proportionality constant was found to improve the overall estimation of  $\beta_{AE}^{\circ}$  values and thus of the theory itself.

Following the formulation of the CNDO/2 parameterization, Pople, Beveridge, and Dobosh proposed the intermediate neglect of differential overlap (INDO) method<sup>2</sup> to alleviate problems in the CNDO calculation for open-shell systems. The CNDO method frequently does not account for separation of states arising from the same configuration, nor, in some cases, does it yield spin densities in the  $\sigma$  orbitals of open-shell molecules.<sup>2</sup> Each of these problems is closely related to the neglect of the two-electron exchange integral

$$(78) \langle \mu\nu | \mu\nu \rangle = \iint \phi_{\mu}(1) \phi_{\mu}(2) \frac{1}{r_{12}} \phi_{\nu}(1) \phi_{\nu}(2) d\tau_1 d\tau_2 \quad \left\{ \begin{array}{l} \mu, \nu \\ \phi_{\mu}, \phi_{\nu} \text{ on } A \end{array} \right\}$$

For this reason the INDO method retains monotonic differential overlap in one-center integrals. In this way the elements of the Fock matrix are modified by

$$(79) F_{\mu\mu} = U_{\mu\mu} + \sum_{\lambda \in A} [P_{\lambda\sigma} (\mu\mu | \lambda\sigma) - 1/2 P_{\lambda\sigma} (\mu\lambda | \mu\sigma)] + \sum_{B(+A)} (P_{B\sigma} - Z_B) \gamma_{AB} \quad (\mu \text{ on atom } A)$$

$$(80) F_{\mu\nu} = U_{\mu\nu} + \sum_{\lambda \in A} [P_{\lambda\sigma} (\mu\nu | \lambda\sigma) - 1/2 P_{\lambda\sigma} (\mu\lambda | \nu\sigma)] \quad \left\{ \begin{array}{l} \mu, \nu \\ \phi_{\mu}, \phi_{\nu} \text{ on } A \end{array} \right\}$$

and

$$(81) F_{\mu\nu} = 1/2 (\beta_A^{\circ} + \beta_B^{\circ}) S_{\mu\nu} - 1/2 P_{\mu\nu} \gamma_{AB} \quad \left\{ \begin{array}{l} \mu \text{ on } A \\ \nu \text{ on } B \end{array} \right\}$$

The above formulation of the INDO Fock matrix elements is based on closed-shell theory since this is the main concern of the entire paper. However, the basic application is to open-shell molecules because in general the CNDO and INDO results are very similar for closed-shell systems.<sup>15</sup> For a sample comparison

DR.RUPNATHJI( DR.RUPAK NATH )

of CNDO and INDO calculations on the same molecule, the reader is referred to appendix A.

The INDO theory has not been implemented for molecules containing atoms of the second row. Its use, therefore, is still limited to atoms H through F.

In spite of the above limitations the CNDO and INDO theories have been applied to a wide variety of problems. One obvious area of concentration has been the determination of the equilibrium geometries of molecules through minimization of the total energy. Calculations of this sort involve systematic variation of the molecular coordinates. Through application of either of these theories equilibrium bond angles as well as bond lengths may be determined.

CNDO/2 calculations of equilibrium geometries have been reported for diatomic,  $AB_2$ , and  $AB_3$  molecules.<sup>12</sup> Comparison of theoretical results with experimental bond lengths and bond angles is, on the whole, encouraging. Pople and Gordon have continued such calculations and comparisons, using INDO theory and systematically studying molecules containing the atoms H, C, N, O, and F with one or two polyvalent atoms (C, N, or O).<sup>16</sup> If A and B represent polyvalent atoms and X and Y represent H and F, the categories of molecules they studied are  $AX_2$ ,  $AXY$ ,  $AX_3$ ,  $AX_2Y$ ,  $AX_4$ ,  $AX_3Y$ ,  $AX_2Y_2$ ,  $XAB$ ,  $X_2AB$ ,  $XAAX$ ,  $X_2AEX$ ,  $X_2AAX_2$ ,  $X_3AEX$ ,  $X_3ABX_2$ , and  $X_3AAX_3$ . Their results also indicate that the INDO theory produces calculations which are for the most part in keeping with experimental values.<sup>16</sup> A summary of their results with special emphasis on quantitative variance from experimental values may be found in

DR.RUPNATHJI( DR.RUPAK NATH )

Pople and Beveridge, Approximate Molecular Orbital Theory (see footnote 4, pp. 97-109).

A second application of the CNDO and INDO theories is in the calculation of electronic charge distribution. The diagonal element  $P_{\mu\mu}$  of the density matrix represents the electronic population of atomic orbital  $\phi_{\mu}$ . A summation of all the electronic populations centered on one atom yields the electronic population of that atom.

$$(82) P_{AA} = \sum_{\mu}^A P_{\mu\mu}$$

Dipole moment is a molecular property closely related to the electronic charge distribution. In the CNDO and INDO approximations, dipole moment is considered to be the sum of two contributions, one from the net charges at the nuclear positions and one which is a hybridization term involving the displacement of the charge away from the center of the nucleus.<sup>1,2</sup>

$$(83) \mu = \mu_{\text{chg}} + \mu_{\text{hyb}}$$

$$(84) \mu = 2.5416 \sum_A \Delta P_{AA} R_A \text{ debyes}$$

$$(85) (\mu_{\text{hyb}})_x = -14.674 \sum_A^* j_A^{-1} P_{2s_A} P_{2p_{xA}} \text{ debyes}$$

In equation (84)  $\Delta P_{AA}$  is the net atomic charge ( $\sum_A - P_{AA}$ ), and  $R_A$  is the position vector of nucleus A. In equation (85)  $j_A$  is the Slater orbital exponent of valence orbitals on atom A, and the asterisk indicates that the summation is restricted to atoms other than H.

Pople and Segal as well as Pople and Beveridge report CNDO/2 dipole moment calculations for  $AB_2$  and  $AB_3$  type molecules<sup>12,17</sup> which correlate well with experimental values. They report also that

DR.RUPNATHJI( DR.RUPAK NATH )

a comparison of CNDO and INDO calculations reveals that the inclusion of the one-centered exchange integral has little effect on dipole moment calculations. In all the above cases dipole moments were calculated for molecules with an equilibrium configuration as determined by CNDO or INDO theory.

Another completely different approach from the two discussed above utilizes standard bond angles and bond lengths, assuming that they closely approximate true equilibrium geometries and can therefore give meaningful results for other molecular properties. Pople and Gordon discuss this approach and propose a set of standard bond lengths and bond angles to be used in such calculations.<sup>18</sup>

Molecular properties of larger molecules may be calculated in this manner, and Pople and Gordon have computed LCAO molecular orbitals, charge distributions, and dipole moments from standard geometries for many organic molecules.<sup>18</sup> They have found that the agreement between experimental and calculated dipole moments is good, with few exceptions. One problem in their comparison, however, is that their assumed standard geometries sometimes differ from those determined by spectral data in a microwave determination of dipole moment. Pople and Beveridge outline the findings of Pople and Gordon,<sup>19</sup> summarizing their significance with respect to theories of electron displacement. Among the molecules discussed are simple nonpolar hydrocarbons, fluorine compounds, oxygen compounds, nitrogen compounds, and mixed compounds of nitrogen, oxygen and fluorine.

Further general applications involving INDO theory and

DR.RUPNATHJI( DR.RUPAK NATH )

open-shell molecules include calculations of electron spin-nuclear spin interactions,<sup>20</sup> spin densities,<sup>2</sup> hyperfine coupling constants,<sup>20</sup> and nuclear spin-nuclear spin interactions.<sup>21</sup> These applications specifically refer to free radicals, radical cations, and radical ions - paramagnetic molecules - and only INDO theory as discussed above will yield tenable results due to its inclusion of the one-center exchange integral.

Other applications of the CNDO/2 theory include a wide range of interesting problems. Several independent studies of substituent effects have been reported. Examples are a CNDO/2 calculation of substituent effects on localization,<sup>22</sup> a CNDO/2 study of the effect of the methyl group on the charge distribution and relative stabilities of conjugated carbonium ions,<sup>23</sup> and a calculation of the inductive effect of the methyl group.<sup>24</sup> Recent structural calculations using CNDO theory include calculations for a series of carbonium ions,<sup>25</sup> for intermediates and transition states in electrophilic substitution,<sup>26</sup> and calculations for p-benzoquinone<sup>27</sup> as well as for trans- and cis-diimides.<sup>28</sup> Also, comparisons of spectral analyses and CNDO calculations have been carried out by Sadlić and Keckli<sup>29</sup> and by Brownlee and Taft.<sup>30</sup> The latter study attempts to correlate the effect of substituents on charge distribution in fluorine molecular orbitals with fluorine proton shifts in NMR spectra.

The above are only selected references to interesting applications of CNDO and INDO theory. Since their development less than ten years ago the two theories have been widely used. One common feature of many of the applications to this point, however, has been a prevalent inherent skepticism as to the quantitative

DR.RUPNATHJI( DR.RUPAK NATH )

accuracy of the calculated results. Thus, often an author uses other experimental findings to corroborate CNDO or INDO calculations and to justify his choice of one of the two theories for his structural framework. A great deal of experimental work has therefore been involved with proving that structure, dipole moments, and other calculated properties do correlate well with experimental data. Such work first showed the inadequacies of the CNDO theory in certain situations and led to the development of INDO theory.

In my opinion, one cannot emphasize enough that these are approximate molecular orbital theories and therefore cannot be expected to be perfectly in keeping with experiment for every calculation. The theories themselves have areas in which improvement is possible. A study on the possibility of improving the estimation of  $\beta$  parameters has been reported.<sup>31</sup> Further, specific areas of the theory have been investigated resulting, for example, in a proposal for substitution of semiempirical coulomb integrals for those originally proposed.<sup>32</sup> In the same study the authors also suggest the introductions of a new empirical parameter to differentiate resonance integrals between  $\sigma$  orbitals and those between  $\pi$  orbitals.

Because of the approximate nature of the theories, use of data for qualitative rather than quantitative predictions seems to be theoretically more meaningful. With further improvement in the CNDO and INDO methods, quantitative use of calculations is likely to become more feasible. In their present form, however, both methods represent a significant advance over other less

DR.RUPNATHJI( DR.RUPAK NATH )

sophisticated theories, specifically those dealing only with  $\pi$  electrons rather than with an entire valence set of basis functions.

DR.RUPNATHJI( DR.RUPAK NATH )

DR.RUPNATHJI( DR.RUPAK NATH )

### III - IMPLEMENTATION OF THE CNDO AND INDO THEORIES

A computer program designed for CNDO and INDO calculations was obtained from Dr. Paul A. Dobosh although it is also available through the Quantum Chemistry Program Exchange, Department of Chemistry, Indiana University, Bloomington, Indiana. In the following pages the features of the original program will be discussed, as well as the modifications necessary to adapt the program to a National Cash Register Century 200 computer with a memory size of 64K.

The program offers the user an option of selecting either the CNDO or INDO general theory for computation and performs calculations for open or closed-shell systems. The CNDO/2 parameterization is used in all CNDO calculations. The maximum size molecule that the program can accommodate is one with 35 atoms or 80 basis functions (or both). All elements through Cl may be included in the molecule if the CNDO method is chosen. If the INDO method is desired, only elements through F may be included in the molecule. INDO theory is implemented in appropriate sections of the program by an optional INDO set of calculations which makes corrections to matrix elements calculated by the CNDO method. In both the CNDO and INDO options, the basis functions assigned to each atom correspond to the minimum basis set or valence orbitals of the atom.

The program is structured into subroutines, each of which performs one of the calculations required by the CNDO or INDO theory. The main program, which appears first, serves only to input the data, convert the coordinates from angstroms to atomic

DR.RUPNATHJI( DR.RUPAK NATH )

units and call the subroutines necessary to complete the calculation. The "COMMON" statement of the Fortran language is used throughout the program to store information in a labeled section of the computer's memory; through use of this feature the information can be accessed by all subroutines, and the computations performed by one subroutine can be passed on to other independent parts of the program. For example, the statement "COMMON/INFO/NATOMS, CHARGE, MULTIP, AN(35), C(35,3)" stores the values of the number of atoms, the charge of the molecule, the multiplicity, and the arrays of atomic numbers and coordinates. At any point in the entire operation of the program this information will be located in a particular block of memory known as "INFO" and can be accessed by any subroutine. Data calculated in subroutines but not stored in such a common memory space is lost when control is returned to the main program unless the subroutine is parameterized in some way.

In the original program the subroutine COEFFT serves to store the values of the coefficients needed in the calculations of the coulomb and overlap integrals. The subroutine INTGRL accomplishes these computations through application of the methods described in the theoretical section. INTGRL calls subroutines RELVEC, SS, HARMTR, and MATOUT while SS calls subroutines AINTGS and BINTGS. From this it can be seen that a major portion of the program is involved with the calculation of the overlap and coulomb matrices. RELVEC serves to calculate the unit vector distance along an interatomic axis between pairs of basis functions, each pair of basis functions giving rise to an overlap matrix

DR.RUPNATHJI( DR.RUPAK NATH )

element PAIRS (I,J). Each basis function is paired with all the other basis functions of the molecule; thus the overlap matrix for HF, with 5 basis functions, is 5 X 5. The function SS, called in the calculation of the non-zero matrix elements, computes the reduced overlap integral discussed in the theoretical section. Following computation, a rotation matrix calculated by HARMTR transforms the integrals to a molecular basis, and the matrix  $S_{\mu\nu}$  is stored in COMMON/ARRAYS/S.

One-center and two-center coulomb integrals are subsequently computed in INTGRL, using, again, the reduced overlap integrals calculated by SS. These integrals are calculated for pairs of atoms, rather than pairs of basis functions, and the matrix is therefore NATOMS X NATOMS in size, where NATOMS represents the number of atoms.

Subroutine HUCKCL initiates an LCAO/SCF-type calculation. The diagonal elements  $F_{pp}$  of a Huckel-like approximation to the Fock matrix are initially replaced by the average of the ionization potential and electron affinity as described in section II. The non-diagonal elements  $F_{\mu\nu}$  are estimated by  $\frac{S_{\mu\nu}}{2} (\beta_A^0 + \beta_B^0)$ , where  $S_{\mu\nu}$  is the overlap integral matrix calculated in INTGRL. The Fock matrix is diagonalized through use of subroutine EIGN; the eigenvectors thus calculated are used to compute the initial density matrix. This matrix is stored in COMMON/ARRAYS/B. At this point appropriate CNDO or INDO corrections are made to the core Hamiltonian matrix. (Note that the Fock matrix is originally assumed in HUCKCL to be equal to the core Hamiltonian matrix; because the density matrix is considered zero in this first

DR.RUPNATHJI( DR.RUPAK NATH )

approximation,  $F_{\mu\nu} = H_{\mu\nu}$  and  $F_{\mu\mu} = H_{\mu\mu}$ .)

Subroutine SCFCLO is called by the main program immediately after subroutine HUCKCL and is the subroutine in which self-consistency is established through comparison of computed values of electronic energy. The initial density matrix as well as the core Hamiltonian computed in HUCKCL are used to calculate the Fock matrix (see equations (57), (58), and (59) in section II). From this initial Fock matrix an initial electronic energy is calculated (before diagonalization.) Diagonalization of the Fock matrix yields a new set of eigenvectors from which a new density matrix and a new Fock matrix are calculated. A new electronic energy value is computed after the formation of each new Fock matrix, before diagonalization. This value is compared with the old energy value, and the cycle continued if the new energy value is not within  $10^{-6}$  Hartrees of the old energy value. The maximum number of iterations allowed is 25; if this number of cycles is completed the process will terminate regardless of whether the energy values have converged or not. If the energy values do converge the Fock matrix is diagonalized once more and then printed under the label HARTREE-FOCK ENERGY MATRIX.

Subroutine CPRINT computes the binding energy, the dipole moments, and the total energy of the molecule. Subroutines SCFOUT and EIGOUT are printing routines, the first to print one of the arrays in COMMON/ARRAYS/ as designated by a parameter and the second to print eigenvalues of the array in SCFOUT.

The program in appendix B is a complete listing of the modified version of the original program. The reader is referred

DR.RUPNATHJI( DR.RUPAK NATH )

to the comments (statements with a C in the far left-hand column and underlined in red) which are descriptive of the organization of each subroutine as described above. Further comments relating the theory to particular portions of the program are included beside appropriate statements.

Modification of the program to adapt it to our computer facilities seemed at first an easy task. Originally written for an IBM 360/65 digital computer, the program had to be adapted to an NCR Century 200 digital computer. Both computers use very similar versions of FULL FORTRAN IV, the differences being idiosyncrasies of the respective compilers. The features of the original program which required modification included the use of an IMPLICIT REAL \* 8 statement, the file numbers on both WRITE and READ statements, and the use of the DFLOAT function. The IMPLICIT REAL \* 8 (A-H, O-Z) extends the normal precision of all real variables to 8 decimal places. It is not available in NCR FULL FORTRAN IV but a DOUBLE PRECISION statement, which extends the normal precision from 6 to 12 significant figures, may be used instead. Each variable, however, must individually be declared DOUBLE PRECISION because no statement exists in NCR FULL FORTRAN IV which will automatically apply to every real variable. Unless a real variable is expressly declared DOUBLE PRECISION, it will be considered real and allotted one-half as much memory as an equivalent double precision variable. The WRITE file number was changed from 6 to 3 and the READ file number from 5 to 1.

No DFLOAT function exists in NCR FULL FORTRAN IV. The purpose of this function is to convert integer variables to float-

DR.RUPNATHJI( DR.RUPAK NATH )

ing point variables in the event that mixed-mode arithmetic is required in a statement. The problem does not occur in NCR FULL FORTRAN IV because mixed-mode arithmetic is automatically performed; integer variables in mixed-mode expressions automatically become floating-point variables. In every use of the DFLOAT function, simply removing "DFLOAT" results in the correct NCR statement.

Adapting the program first for closed-shell molecules only, we made the above changes and ran the computer program using data for hydrogen fluoride. After correcting some minor syntax errors, we obtained a successful compilation with the message "PROGRAM EXCEEDS SIZE" as we had expected. The program in its original form with the above modifications requires approximately 170,000 bytes of memory for the COMMON memory alone, while the NCR Century 200 has only 64K (actually 65,456) bytes of memory space available. The problem, then, was one of reducing the amount of memory needed for COMMON by more than two-thirds.

In NCR FULL FORTRAN IV each double precision variable requires 8 bytes of memory space. An obvious way of reducing the memory size was to reduce the size and number of the double precision arrays in COMMON. We therefore reduced the maximum number of atoms from thirty-five to ten and the maximum number of basis functions from eighty to twenty-five. This change reduced the size of COMMON/ ARRAYS/ from 19,200 to 1875, COMMON/INFO/ from 144 to 44, COMMON/ GAB/ from 2000 to 875, and COMMON/INFO1/ from 188 to 58. As each of the variables reduced was a double precision array, a total of 131,840 bytes of memory was released by these changes. Further, the arrays G1(18), F2(18), BETA0(18), and ENEG(18,3) in subroutine

DR.RUPNATHJI( DR.RUPAK NATH )

HUCKCL were originally declared DOUBLE PRECISION. The values assigned to elements of these arrays, however, never require more than 6 decimal places of precision. Because of the NCR's capacity to perform mixed-mode arithmetic, we were able to declare all these arrays single precision and to save 432 bytes of memory.

COMMON/ARRAYS/ serves in the original program as a storage place for the Z and Y coefficients used in calculation of the reduced overlap integrals. In COEFFT a total of 765 Z values were input, of which 678 were zero. 9135 Y values were input, of which 8811 were zero. All Y and Z values were declared double precision. From this it seemed obvious that a majority of the storage space required by COEFFT retained zero values. In order to reduce further the memory required by the program, we therefore removed the subroutine COEFFT entirely and devised a method of reading in as data the non-zero Z and Y coefficients.

In this method two parallel arrays are constructed for both Z and Y values. The first array consists of the array element numbers of non-zero Z values (or of non-zero Y values.) This array is called NZZ (or NZY), meaning non-zero Z (or non-zero Y). The second parallel array NZZV (or NZYV), non-zero Z value (or non-zero Y value) is composed of the actual values corresponding to the array element numbers in NZZ and NZY. For example, if Z(1) was originally input in COEFFT as Z(1)=64, in the modified version of the program NZZ(1)=1 and NZZV(1)=64. Cards from the original program are used for inputting the Z and Y values. The values are read and stored in the MAIN segment of the program. NZZ, NZZY, NZY, and NZYV are all allotted to COMMON/ARRAYS/ to be accessible to other parts of the program.

DR.RUPNATHJI( DR.RUPAK NATH )

In function SS the value of Z or of Y to be used in computation was originally determined by an array element number which was a function of the variables of two "DO" loops. Thus,  $X = X + Z(I+1,L) * A(I+1) * B(NNI1)/2.DO$  or  $X = X + Y(I+1,J+1,L) * A(I+1) * B(IIII)$ . Using the rule for array element succession in FULL FORTRAN IV, we converted these into linear array element numbers. According to this rule, if Z is an array of size 17 X 45, Z(I+1,L) is equivalent to Z(I+1+17\*(L-1)). If Y is a 9 X 5 X 203 array, Y(I+1,J+1,L) is equivalent to Y(I+1+9\*J+5\*(L-1)). A systematic comparison of the desired Z or Y array element numbers with those stored in NZZ or NZY reveals whether the desired element is one of the non-zero elements. If so, Z is assigned the value of the corresponding NZZV or NZZY element. If not, it remains zero.

This modification requires the addition of NZZ(87), NZZV(87), (NZY(224), and NZYV(224) to COMMON/ARRAYS/ but allows the reduction in the number of basis functions without loss of memory space required for storage of Y or Z coefficients. The process undoubtedly involves more computer time, but in our case free memory space was the alternative to efficiency that we preferred.

In spite of the above modifications the program failed to run properly. Memory was approximately at the 64K limit and did not seem to be the problem. For this reason we attempted to use a trace statement to get a printout of all variable values throughout the program but found that this feature of NCR FULL FORTRAN IV had not been implemented in our compiler. Inserting write statements in appropriate spots, we saw that the program was failing somewhere in subroutine INTGRL due to what the computer termed

DR.RUPNATHJI( DR.RUPAK NATH )

an exponential overflow.

For several months we investigated this problem, approaching it from as many different angles as possible. One such approach revealed by accident an obvious error in the computer rather than in our program. We had considered the possibility that the complicated overlay of the program was causing the problem and decided to structure the program into two independent but LINKed programs (using the LINK feature of FORTRAN), the first containing subroutine INTGRL and the subroutines used in INTGRL and the second containing the other subroutines. We found, using this LINK procedure, that the output of the linked and non-linked programs were not equivalent but that neither program worked! We concluded that the memory overlay was not the problem but rather some inherent computer error. We sent copies of both programs to National Cash Register headquarters in Dayton, Ohio, and after several weeks of testing they confirmed that an error in the floating-point hardware of our computer was preventing the program from running correctly.

After correction of the problem we input data for formaldehyde,  $\text{CH}_2\text{O}$ , and concentrated on the first part of the program which calculates coulomb and overlap integrals. The matrices were calculated by the program but additional output from test write statements revealed another computer error. The  $l$  quantum numbers were appearing consistently as negative values. It was obvious since these are all positive integers that at least one calculation was incorrect. We carried through computations by hand and found no problem, concluding again that there was a software or hardware error. Subsequent test runs in Dayton showed that the

DR.RUPNATHJI( DR.RUPAK NATH )

error was reproducible on other NCR Century 200 computers and that it thus was not a localized problem of the computer available to Sweet Friar. In the process of investigating this error, problems in the exponentiation procedure and in the double precision hardware were found. These, however, were not the causes for assignment of negative values to the l quantum number. This remains unsolved, though accidentally we discovered a way to overcome it.

In the calculation of PAIRS(I,J) the non-zero overlap matrix elements computed in INTGRL, a rather complex mathematical statement is employed.

```
(1) PAIRS(I,J)=DSQRT((MU(ANK)*R)**(2*NC(ANK+1)*(MU(ANL)*R)**(2*NC(ANL+1)/FACT(2*NC(ANL))))*(-1.DO)**LC(J)+MC(J))*SS(NC(ANK), LC(I), MC(I), NC(ANL), LC(J), MU(ANK)*R, MU(ANL)*R)
```

Suspecting that the argument of the DSQRT function was becoming negative we broke this statement down as follows:

```
(2) NEWV=((MU(ANK)*R)**(2*NC(ANK)+1)*(MU(ANL)*R)**(2*(NC(ANL+1)/FACT(2*NC(ANL)))))
```

```
(3) NEWS = SS(NC(ANK), LC(I), MC(I), NC(ANL), LC(J), MU(ANK)*R, MU(ANL)*R)
```

```
(4) PAIRS(I,J) = DSQRT(NEWV)*(-1.DO)**((LC(J)+MC(J))*NEWS
```

In addition we added the following loop:

```
IF (NEWV LE. 0) GO TO 135
```

```
135 DSQRT(NEWV) = 0
```

```
WRITE (3, 145) NEWV
```

The above statements were placed before the final PAIRS(I,J) statement so that the possibility of extracting the square root of a negative number was eliminated. After the floating-point hardware

DR.RUPNATHJI( DR.RUPAK NATH )

was corrected, a printout for HF was obtained which did not assign a negative value to l. In a subsequent run on formaldehyde, the original PAIRS(I,J) statement was restored, resulting in the original assignment or calculation error. Again breaking up PAIRS(I,J) as described, we were able to obtain a successful printout for the first part of the program - one which correlated almost exactly with a good run on formaldehyde using the original computer program adapted to a CDC 5400 computer at the University of Virginia.

The second half of the program was tested independently of the first by inputting the correct overlap and coulomb matrices and making other necessary modifications. Printout for this half of the program using data for formaldehyde corresponded to the correct printout on the CDC 6400.

The two programs were then recompiled into one and run, using double precision variables and inputting data for formaldehyde. This trial run produced correct results.

Once the program was running properly a further modification was made to increase the number of allowed basis functions from 25 to 31. ~~COMMON/ARRAYS/~~ originally allotted enough memory space for 3 arrays with dimensions equal to the number of basis functions squared. Inspection revealed that the third of these arrays was used only in calculations for open-shell molecules; since this option is not a feature of the modified program this array was eliminated, resulting in enough free memory space to increase the maximum number of basis functions to 31.

The modified program in its final form can perform CNDO and INDO calculations on closed-shell molecules with a maximum size

DR.RUPNATHJI( DR.RUPAK NATH )

of 10 atoms and 31 basis functions. The CNDO option may be chosen for molecules containing atoms through Cl and the INDO option for molecules with atoms through F. The language in which the program is written is NCR FULL FORTRAN IV, and the total memory required is approximately 65,000 bytes. Output from the program includes the overlap matrix, the coulomb matrix, the density matrix, the Hartree-Fock energy matrix, the total, the electronic and the bonding energies of the molecule as well as the total dipole moment and contributions from components.

In conclusion, in the process of modifying the program my own personal attitude about computer calculations was reversed - from one of complete trust to one of innate skepticism; when errors appeared in the program throughout the year they seemed to be due chiefly to the inadequacies of the computer rather than logical or syntax problems on my part. One definite finding of the project is that the NCR CENTURY 200 computer with a FULL FORTRAN IV compiler is not the best machine available to handle programs of the size and complexity of the one with which we were dealing.

DR. RUPNATHJI (DR. RUPAKNATH)

DR.RUPNATHJI( DR.RUPAK NATH )

#### IV - EXPERIMENTAL

Brownlee and Taft have used the CNDO/2 method to study substituted fluoroacetylenes and trans-substituted fluoroethylenes.<sup>30</sup> With the recent extension of CNDO/2 theory to include atoms of the second row of the periodic table,<sup>14</sup> it is possible to compare results such as those obtained by Brownlee and Taft to results using substituted chloroacetylenes and substituted chloroethylenes. Such a comparison can yield at least a qualitative measure of the relative electronic effects of fluorine and chlorine.

Though fluorine and chlorine are both in the halogen series, the difference between the two is greater than between succeeding heavier halogens. Fluorine is a smaller atom, having a covalent radius of 0.72 Å, while chlorine has a covalent radius of 1.00 Å. The valence shell configurations of the two are  $2s^2 2p^5$  and  $3s^2 3p^5$  respectively. Fluorine is the most electronegative of all the elements, having an electronegativity of 3.95 on the Pauling scale, and chlorine's electronegativity is 3.03. Related to electronegativity is the inductive effect parameter  $\sigma_x$ <sup>33</sup> which is 0.52 for F and 0.47 for Cl. The resonance effect parameter  $\sigma_R$ <sup>34</sup>, measuring the tendency of a substituent to delocalize  $\pi$  electrons, is -0.45 for F and -0.24 for Cl.

The above characteristics of fluorine and chlorine lead to some interesting differences in the bonding properties of the two atoms. Because of fluorine's smaller size, it has a higher charge density than does chlorine. Such a high charge density results in a large measure of repulsion among the lone-pair electrons on the atom.

DR.RUPNATHJI( DR.RUPAK NATH )

$\pi$  bond formation reduces some of the charge density due to delocalization, and thus fluorine has a tendency to contribute to  $\pi$  bonds. Chlorine, on the other hand, has a much more dispersed electron population than does fluorine. Its relative contribution to  $\pi$  bonding is therefore less.

A last significant difference mentioned between the two atoms is their electronic configuration. Though each has 2 electrons in the valence s orbitals and 5 in the valence p orbitals, the Cl atom has 5 empty 3d orbitals which contribute in some way to covalent bonding.

From these general differences one may make specific predictions about the relative effects of fluorine and chlorine on electron distribution. Fluorine's greater electronegativity should be evident in a comparison of the  $\sigma$  electron densities at specified atoms in fluoro- and chloro- compounds.

Figure 1.

Referring to figure 1, the excess  $\sigma$  electron density at F in molecule A should be greater than that at Cl in molecule B, and the corresponding  $\sigma$  electron deficit at C<sub>2</sub> in molecule A should be greater than that at C<sub>2</sub> in molecule B. The inductive effects of the two atoms fluorine and chlorine are likely to be observable at the carbon bonded to the substituent, X. Although quantitatively the  $\sigma$  electron density at the substituent carbon C<sub>1</sub> reflects to a large extent the inductive effect of the particular substituent, the greater electronegativity of fluorine

DR.RUPNATHJI( DR.RUPAK NATH )

should result in a smaller absolute electron density at  $C_1$  in molecule A than at  $C_1$  in molecule B.

With respect to  $\pi$  electron distribution, one would expect the total  $\pi$  density at the two ethylene carbons (hereafter referred to as  $\sum_c q_{\pi}$ ) to be less in chloro- compounds than in corresponding fluoro- compounds. The concentration of  $\pi$  electrons at  $C_2$  in molecule A (the carbon bonded to fluorine) should be greater than at  $C_2$  in molecule B (the carbon bonded to chlorine).

To test these predictions a CNDO/2 calculation was done on 6 monosubstituted ethylenes and then subsequently on 4 of the 6 corresponding fluoro- and chloro- compounds. Standard geometries were assumed using the best values from the literature.<sup>35</sup> Though not physically correct, the assumption was made that the substitution of a fluorine or chlorine group does not change appreciably the other bond lengths or bond angles of the molecule. Justification for such an assumption lies in the comparative approach being used. The same standard geometries were used for chloro- and fluoro- compounds - which seems more consistent than varying bond lengths or bond angles based on different experimental values. Also, experimental values were not available for all of the molecules for which calculations were made. The convention was used in which the double or triple bond is along the x axis with the z axis perpendicular to the molecular plane. In this way  $\pi$  electron density can be directly obtained from the charge density matrix, the diagonal  $p_x p_x$  elements representing  $\pi$  contributions of atomic basis functions to the atoms on which they are centered.  $\sigma$  electron density can be calculated and is the sum of the contributions of the diagonal s,  $p_x$  and  $p_y$  elements. The calculated x, y, and z

DR.RUPNATHJI( DR.RUPAK NATH )

coordinates are given in appendix C.

The substituents we originally hoped to consider were F, Cl, CHO, CN, NO<sub>2</sub>, and CH<sub>3</sub>. These represented a wide range within the limitations of the modified CNDO program. We were unable to complete calculations for all the molecules, however.

In the course of investigating this particular problem we discovered another inadequacy of the NCR Century 200 computer. A total of 44 molecules were input (NRUNS=44); after 1½ hours the run was aborted because the operators thought the program was in an infinite loop. In fact, it was in the process of executing computation for one of the more complicated molecules. We therefore broke the data down into two decks and hoped in this way to reduce the length of each job. One of the data decks was run for 9 hours and 45 minutes, after which only 3/4 of the data had been processed. Calculations were completed for only 12 molecules during the two runs; subsequent runs gave results for 3 more molecules. My conclusions, therefore, must be based on findings with respect to this limited number of substituted ethylenes. Time prevented acquisition of data for the remainder of the ethylenes or the acetylenes.

Tables I, II, and III contain excess  $\sigma$  electron densities at specified atoms in monosubstituted ethylenes, substituted fluoroethylenes, and substituted chloroethylenes, respectively. Excess electron density was computed by subtracting the electron density of the appropriate undispersed orbitals from the calculated electron density.

DR.RUPNATHJI( DR.RUPAK NATH )

DR.RUPNATHJI( DR.RUPAK NATH )

Tables I - III are interesting not only for the information they contain concerning the relative electronic effects of fluorine and chlorine, but also concerning the effects of substituents on the inductive abilities of the two atoms. It is useful to note, for example, that in table II the  $\sigma$  electron density at F is almost .02 smaller for a  $\text{NO}_2$  substituted fluoroethylene than for any other substituent. This is an indication of the competition between  $\text{NO}_2$  and F for electrons, and it also points out <sup>that</sup>  $\text{NO}_2$  is the most electronegative of any of the substituents. Similarly, in table III, the electron density at Cl in the nitro- substituted molecule is at least .04 smaller than for other substituents. The fact that the difference is less in the case of the fluoro- compounds than in the case of the chlorine compounds is indicative of the fact that chlorine is less able to compete with  $\text{NO}_2$  for  $\sigma$  electrons; it is less electronegative.

Table IV was tabulated from tables I - III and represents a comparison of the data of the three.

Table IV. A Comparison of  $\sigma$  Electron Densities in Substituted Fluoroethylenes and Chloroethylenes

Cl, CN	-.0318	-.0424	----	.1249

DR.RUPNATHJI( DR.RUPAK NATH )

Table IV is in keeping with theoretical expectations. The greater inductive effect of fluorine is evident in every case considered. For both of the geometrical configurations of CHO- substituted molecules, there is an excess of electron density at the carbon bonded to the substituent; the excess is larger for F than for Cl. This excess represents a redistribution of  $\sigma$  electrons from the substituent to C<sub>1</sub> and reflects the successful competition of fluorine and chlorine for part of the  $\sigma$  electron density of the substituent. This can be illustrated through the following schematic diagram, using the CHO\* configuration:

Figure 2.

(Note that in figure 1  $\delta$  refers to charge rather than electron population. The difference lies only in the sign; an excess electron density results in an excess negative charge. Also,  $|\delta\delta| < |\delta|$ .)

The substituents NO<sub>2</sub> and CN also illustrate the fact that fluorine has a greater inductive effect than chlorine; the substituents however, are both more electronegative than CHO as indicated in figure 3 using the NO<sub>2</sub> group as an example.

Figure 3.

The inductive effects as calculated by CNDO/2 theory are thus in keeping with those predicted. Fluorine's greater electronegativity

DR.RUPNATHJI( DR.RUPAK NATH )

is evident in calculations for pairs of molecules with all 4 substituents, though it is interesting to note the variations in charge distributions that occur because of the electronegativity of the substituent. The relative electronegativities of the substituents as calculated are  $\text{COH} < \text{CN} < \text{NO}_2$  which corresponds to the inductive substituent constant order of  $0.31 < 0.56 < 0.63$  for these substituents, respectively.<sup>36</sup>

F, CN	.0340	.0780	-.0440	-.0581	----
Cl, CN	-.0122	.0420	-.0309	----	-.0305

Table VIII indicates that the  $\pi$  electron distribution at the ethylene carbons is consistently greater for fluoro- com-

DR.RUPNATHJI( DR.RUPAK NATH )

pounds than for chloro- compounds. For each pair of molecules being compared, the deficit of  $\pi$  electrons at fluorine is greater than the deficit at chlorine, indicating that fluorine is making a larger contribution to  $\pi$  bonding than chlorine. The total excess  $\pi$  electron density at the ethylene carbons is also greater for fluoroethylenes than for chloroethylenes.

The actual distribution of the  $\pi$  electrons is an interesting problem. Although one would expect that the  $\pi$  density at  $C_2$  (bonded to fluorine or chlorine) would be greater than at  $C_1$ , the reverse is consistently true. Apparently the  $\pi$  electrons contributed by both fluorine and chlorine in their respective systems appear at  $C_1$ . The explanation for this likely lies in the form of the molecular orbitals, but a detailed analysis is an area for further investigation.

Thus, the calculated  $\sigma$  and  $\pi$  distributions of substituted fluoro- and chloro- compounds reflect the greater inductive and resonance effects of fluorine than chlorine. A definite problem with the framework of this study, however, is the assumption of fixed standard geometries regardless of substitution of the fluoro- or chloro- group. As mentioned previously, the data obtained should be used only in a qualitative study rather than any sort of quantitative assessment of the trends discovered. Whether these trends would be enhanced or reduced by use of actual equilibrium geometries for the given molecules is a problem for further study.

Likewise, the use of only four different sets of molecules from which to draw general conclusions is undesirable. This factor, however, was beyond our control; similar runs for other molecules using the same computer program and the coordinates in appendix

DR.RUPNATHJI( DR.RUPAK NATH )

C may reveal other important results.

The computer program would probably yield more accurate density values if it were modified to achieve self-consistency using an electron density criterion rather than the electronic energy convergence. In the case of larger molecules, in particular, there was some difficulty in obtaining proper convergence using electronic energy. By focusing on one of the elements of the density matrix or on a standard deviation of the diagonal elements, for example, this change could be instituted.

In spite of these limitations, in the three substituted ethylenes investigated the qualitative trends which the data revealed are in keeping with predictions. Because of the assumptions of standard geometries, the limited data available, and the use of electronic energy as a measure of self-consistency rather than charge density, these conclusions must remain, at best, qualitative. Nevertheless, the trends discussed above appeared in each set of data, with no exception.

## V - CONCLUSIONS

The CNDO and INDO methods successfully extend other more approximate molecular orbital theories through the entire valence set of electrons. Based on the ZDO approximation, both methods rely on a self-consistent field method using the LCAO approach. The INDO theory, however, retains one-center monotomic differential overlap in order to improve correlation of theoretical and experimental data for open-shell molecules.

When applied to a series of simple molecules ( $AB$ ,  $AB_2$ ,  $AB_3$ , for example), the CNDO/2 parameterization has been found to be more successful than the CNDO/1 parameterization in that calculated bond lengths and dissociation constants are more in keeping with those experimentally determined. The main difference between the latter and the former is the former's neglect of the penetration integral. This modification was found to improve results considerably.

CNDO/2 theory has recently been modified to include atoms through Cl in the periodic table. This involves the estimation of orbital forms for each of the 5 3d orbitals and the inclusion of a specified empirical constant in the estimation of the resonance integral  $k_{ss}$ . An important area for investigation is the further extension of this theory to the transition elements. Highly symmetric transition metal crystals, could, through group theory, be studied without requiring excessive numbers of basis functions.

Implementation of the CNDO and INDO theories was accomplished through adaptation of a computer program to the NCR Century 200

DR.RUPNATHJI( DR.RUPAK NATH )

computer to which Sweet Briar has access. The problems involved included reducing the large amount of memory space originally required and changing minor syntax idiosyncrasies in the original version of the program. These changes did not result in successful operation but rather led to the discovery of several malfunctions of the computer. We were able to pinpoint and overcome these errors and obtain printouts for  $\text{CH}_2\text{O}$  which reproduced similar runs on another machine.

Having adapted the program, we were able to apply it to a simple problem, an investigation of the effects of F and Cl on  $\sigma$  and  $\pi$  electron densities in substituted fluoro- and chloro-ethylenes. Excessive computer time was required to perform calculations, nine molecules being executed in 9 hours and 45 minutes. For this reason the experiment had to be based on only a part of the molecules we had hoped to run.

Data from these calculations was in keeping with theoretical predictions in every case studied. Fluorine has greater inductive and resonance effects, and this was clearly demonstrated by the data. An area for study, however, is the actual  $\pi$  distribution at each carbon.

The problems encountered in structuring even a simple experiment such as the one we initiated indicate that data should be used to determine qualitative rather than quantitative trends. The CNDO and INDO theories themselves are approximations of other approximate molecular orbital theories, and one should proceed with care when attempting to make quantitative evaluations based on data obtained using these theories. They are, however, important in the development of approximate molecular orbital theories,

DR.RUPNATHJI( DR.RUPAK NATH )

representing two of the most sophisticated and useful methods recently devised. Though at this stage they are still being tested, their application to specific problems is rapidly becoming more widespread; the results of such studies seem very encouraging and suggest a variety of other possible uses of these theories in the future.

DR.RUPNATHJI( DR.RUPAK NATH )

DR.RUPNATHJI( DR.RUPAK NATH )

APPENDIX A

Appendix A contains a CNDO and an INDO calculation for formaldehyde,  $\text{CH}_2\text{O}$ . The two indicate that the differences between the methods result in only small variations in the core Hamiltonian, Hartree-Fock and density matrices. These variations arise from the addition, at several points in the program, of INDO corrections to CNDO matrices. Because the INDO method includes the one-center monatomic differential overlap terms, the INDO calculations probably more closely approximate the true values than do the CNDO calculations.

APPENDIX B

Appendix B contains the modified version of the CNDO-INDO computer program discussed in Section III of this paper. The data which must be input includes the Z and Y coefficients, the number of molecules which are to be executed during each run, the CNDO or INDO option desired, that the molecule has a closed-shell (only closed-shell molecules can be accommodated by the program), the number of atoms in the molecule, its charge, multiplicity, and X, Y, and Z coordinates with respect to the coordinate system chosen for the molecule. The data is input in the following way:

- CARDS 1-87 - NZZ and NZZV (Format (8X,I3,2X,I6))
- CARDS 88-311 - NZY and NZYV (Format (8X,I4,2X,I6))
- CARD 312 NRUNS (Format (I2))
- CARD 313 - An identification card with any format
- CARD 314 - OPTION (wavefunction option) and OPNCLD  
(The key words are CNDO or INDO and CLSD.  
The format is (A4,1X,A4))
- CARD 315 - NATOMS, CHARGE, MULTIP (Format (3I4))
- CARDS 316 - Atomic number, X coordinate, Y coordinate,  
and Z coordinate - 1 card/atom  
The format is (I4,3(3X,F12.7))

DR. RUPNATHJI (DR. RUPAK NATH)

Was the problem area. We created variables NEWV and NEWS to break up PAIRS(I,J) in  
 statement 130. PAIRS(I,J) are the overlap integral matrix elements.

DR.RUPNATHJI( DR.RUPAK NATH )

APPENDIX C

Below are the x, y, and z coordinates for a series of monosubstituted acetylenes and ethylenes as well as substituted fluoro- and chloro- acetylenes and ethylenes.

1. Monosubstituted Acetylenes

Assumptions: a) C≡C bond length is fixed at 1.204 Å  
 b) Substitution does not change the C≡C length

	x	y	z
C <sub>1</sub>	0.000	0.000	0.000
C <sub>2</sub>	-1.204	0.000	0.000
H	-2.26	0.000	0.000
X= H	1.06	0.000	0.000

O	0.605	-1.048	0.000

4. Monosubstituted Ethylenes

- Assumptions: a) C=C bond length of 1.337 Å  
 b) Substitution does not change molecular geometry  
 c) Trigonal bonds

C	0.000	0.000	0.000
C	-1.337	0.000	0.000

DR.RUPNATHJI( DR.RUPAK NATH )

H <sub>1</sub>	0.540	0.935	0.000
H <sub>2</sub>	-1.88	0.935	0.000
H <sub>3</sub>	-1.88	-0.935	0.000
X=H	0.540	-0.935	0.000
X= F	0.674	-1.28	0.000
X= Cl	0.865	-1.50	0.000

X= CHO (trans)\*

C	0.779	-1.229	0.000
O	1.991	-1.229	0.000
H	0.199	-2.140	0.000

X=CN.

C	0.730	-1.26	0.000
N	1.310	-2.27	0.000

X=NO<sub>2</sub> (planar)

N	0.735	-1.27	0.000
O	1.34	-2.32	0.000
O	1.945	-1.27	0.000

X=NO<sub>2</sub> (not planar)

(This was the most stable configuration and was used in the tables in Section IV)

N	0.735	-1.27	0.000
O	1.0375	-1.797	-1.048
O	1.0375	-1.797	-1.048

X=CH<sub>3</sub>

C	0.745	-1.29	0.000
H	0.0302	-2.126	0.000
H	0.9566	-1.888	0.367
H	0.9566	-1.888	-0.367

-----\*\*  
For X=CHO (cis) the following geometry was assumed:

C <sub>1</sub>	0.000	0.000	0.000
C <sub>2</sub>	-1.16	0.669	0.000
H <sub>1</sub>	-2.093	0.129	0.000
H <sub>2</sub>	0.000	-1.08	0.000
H <sub>3</sub>	-1.16	1.75	0.000
H <sub>4</sub>	-2.16	0.239	0.000
C	1.223	0.779	0.000
O	1.223	1.991	0.000
H	2.164	0.239	0.000

DR.RUPNATHJI( DR.RUPAK NATH )

5. Substituted Fluoro- Ethylenes

Assumptions: see (4)

(c) All substitutions are trans- unless otherwise stated

To obtain these molecules the following is substituted for

H <sub>2</sub>	-1.88	0.935	0.000	:
F	-1.992	1.135	0.000	

For cis CHO

H <sub>1</sub>	-2.093	0.1285	0.000	
----------------	--------	--------	-------	--

was replaced by

F	-2.28	0.135	0.000	
---	-------	-------	-------	--

6. Substituted Chloro- Ethylenes

Assumptions: see (4) and (5)

To obtain these molecules the following is substituted for

H <sub>1</sub>	-1.88	0.935	0.000	:
Cl	-2.197	1.500	0.000	

For cis- CHO

H <sub>1</sub>	-2.093	0.1285	0.000	
----------------	--------	--------	-------	--

was replaced by

Cl	-2.747	0.215	0.000	
----	--------	-------	-------	--
